## Non-probability sampling phone survey

---

**(b)**

I called 112 numbers. 13 people over 18 years old responded, and 99 numbers were not responded or the responder was below 18. The respond rate is 11.61%.

**(c)**

Among the 13 responders, 10/13 of them answered the age question and 10/13 of them answered the voting question.

**(d)**

I called during 7pm and 9pm, when most people were off work and not sleeping. This timing might have increased my respond rate, otherwise fewer people would respond if they were working or sleeping.

**(e)**

The median age of my respondents is 30, which is lower than the median age in Pennsylvania, 40.4. Maybe this is because more young and middle-aged people use cellphones so they are more likely to respond to my call. Also, a sample of 10 is too small to represent the population.

**(f)**

4(40%) of my respondents voted Republican (Trump) in the 2016 U.S. Presidential election. While 5(50%) of my respondents voted Democrat (Clinton). 1(10%) of them did not vote. Comparing to the actual voting percentages in Pennsylvania from the 2016 election (48.18% Republican and 47.46% Democrat), Republican's voting percentage is relatively lower in my sample, while Democrat's voting percentage is relatively higher.

To test if the order in which I say the candidates or categories in the survey question influences the results, I need to randomly call another 10 people and ask the survey question in a different order. Then compare the voting fractions of the two samples and see if there's a difference. Repeating this experiment several times (or having larger samples) can give more confident result.

## **(a)**

Of the eight variables reported from the respondents, sex, age and education from the Xbox sample are the least representative of the data. While race, state and 2008 vote are the most representative. Sex and age are the least representative because young men dominate the Xbox users. Men make up 93% of the Xbox sample but only 47% of the electorate; 18- to 29-year-olds comprise 65% of the Xbox dataset, compared to 19% in the exit poll. That there are fewer college graduates in the Xbox population suggests that Xbox users generally have a lower education level than the voting population. Possibly because many Xbox users are too young to graduate from college.

## **(b)**

When the authors performed a post-stratification re-weighting of the respondents, they need to divide the population into cells by all possible combinations of the variables in the Xbox survey, and calculate the weights of each cell by the proportion of the electorate in each cell. They used exit poll data from the 2008 presidential election to obtain the weights, and then applied the weights to the Xbox survey data.

## **(c)**

According to Fig. 2, the Xbox raw data would have predicted that Romney would win during the last three weeks before 2012 U.S. Presidential election, since the two-party Obama support was significantly below 50% in Xbox raw data. Pollster.com forecast data would have predicted that the election outcome as uncertain during the last three weeks before election, since the two-party Obama support was very close to 50% in that period. According to Fig. 3, the Xbox post-stratified data would have predicted that Obama would win during the last three weeks before 2012 election, since the two-party Obama support was significantly above 50% in Xbox post-stratified data.
